# Package 'sleepr'

October 29, 2020

Title Analyse Activity and Sleep Behaviour	
<b>Date</b> 2018-10-04	
Version 0.3.0	
Description Use behavioural variables to score activities It is primarily designed to score sleep in fruit flicies) and Ethoscope data.  It implements sleep scoring using the ``fiveminute rule" (Hendricks et al. (2000) <doi:10. (2017)="" (geissmann="" <doi:10.1371="" activity="" al.="" classific<="" classification="" et="" ethoscopes="" for="" journal.pbio.activity="" td=""><td>es from Drosophila Activity Monitor (TriKinet-1016/S0896-6273(00)80877-6&gt;),</td></doi:10.>	es from Drosophila Activity Monitor (TriKinet-1016/S0896-6273(00)80877-6>),
<b>Depends</b> R (>= 3.00), behavr	
Imports data.table

bout\_analysis

Index 8

bout\_analysis

Find "bouts" in categorical time series

# **Description**

This function is used to find contiguous regions of unique value in a – potentially irregular/heterogeneous – univariate categorical time series.

# Usage

```
bout_analysis(var, data)
```

# Arguments

var name of the variable to use from data

data data.table containing behavioural variable from or one multiple animals. When

it has a key, unique values, are assumed to represent unique individuals (e.g. in a behavr table). Otherwise, it analysis the data as coming from a single animal.

data must have a column t representing time.

#### Value

an object of the same type as data (i.e. data.table::data.table or behavr::behavr). Each row is a specific bout characterised by three columns.

- t its *onset*
- duration its length
- <var> a column with the same name as var. The value of var for this bout.

#### References

• The relevant rethomic tutorial section – on sleep analysis

# See Also

- sleep\_annotation to generate a binary sleep variable
- rle run length encoding function on which this analysis is based

curate\_dead\_animals 3

#### **Examples**

curate\_dead\_animals

Remove - irrelevant - data after individual have died

# Description

This function detects when individuals have died based on their first (very) long bout of immobility. Following data (which may include spurious artefact of movement) are removed.

#### Usage

```
curate_dead_animals(data, moving_var = moving, time_window = hours(24),
   prop_immobile = 0.01, resolution = 24)
```

#### **Arguments**

data	data.table containing behavioural variable from or one multiple animals. When it has a key, unique values, are assumed to represent unique individuals (e.g. in a behavr table). Otherwise, it analysis the data as coming from a single animal. data must have a column t representing time.
moving_var	logical variable in data used to define the moving (alive) state (default is moving)
time_window	window during which to define death (default is one day)
<pre>prop_immobile</pre>	proportion of immobility that counts as "dead" during time_window (see details)
resolution	how much scanning windows overlap. Expressed as a factor (see details).

#### **Details**

This function scans the time series looking for "death" in the right (future) data, within time\_window. Death is defined as mean(moving\_var) < prop\_immobile within a time window. Moving window start every time\_window/resolution. resolution = 1 is fast but means no overlap. The default would score an animal as dead it does not move more than *one percent of the time* for at least *one day*. All data following a "death" event are removed.

4 motion\_detectors

#### Value

an object of the same type as data (i.e. data.table::data.table or behavr::behavr).

# See Also

• sleep\_annotation – to score movement and slepe

# **Examples**

```
dt1 <- toy_activity_data()</pre>
#all movement after day 3 is set at 0
dt1[t > days(3), moving := FALSE]
# one artefact of movement is detected at day 3.5
dt1[t == days(3.5), moving := TRUE]
dt2 <- curate_dead_animals(dt1)</pre>
dt3 <- curate_dead_animals(dt1,prop_immobile = 0)</pre>
## Not run:
library(ggplot2)
ggplot(data=dt1[,test:=1],aes(t, as.numeric(moving))) +
  geom_line(data=dt1[,test:=1]) +
  geom_line(data=dt2[, test:=2])+
  geom_line(data=dt3[, test:=3])+
  facet_grid(test ~ .)+
  scale_x_time()
## End(Not run)
```

motion\_detectors

Motion detector for Ethocope data

#### **Description**

Defines whether a single animal is moving according to:

### Usage

```
max_velocity_detector(data, time_window_length,
    velocity_correction_coef = 0.003, masking_duration = 6)
max_velocity_detector_legacy(data, velocity_threshold = 0.006)
virtual_beam_cross_detector(data, time_window_length)
```

motion\_detectors 5

#### **Arguments**

data

data.table::data.table containing behavioural variables of *a single animal* (no id). It must have the columns xy\_dist\_log10x1000(for computing subpixel velocity), x(beam cross), t and has\_interacted (whether a stimulus was delivered).

time\_window\_length

number of seconds to be used by the motion classifier. This corresponds to the sampling period of the output data.

velocity\_correction\_coef

an empirical coefficient to correct velocity with respect to variable framerate.

masking\_duration

number of seconds during which any movement is ignored (velocity is set to 0) after a stimulus is delivered (a.k.a. interaction).

velocity\_threshold

uncorrected velocity above which an animal is classified as 'moving' (for the legacy version).

#### **Details**

- Validated and corrected subpixel velocity (max\_velocity\_detector), the most rigorous
- Uncorrected subpixel velocity (max\_velocity\_detector\_legacy)
- Crossing a virtual beam in the middle of the region of interest (virtual\_beam\_cross\_detector)

max\_velocity\_detector is the default movement classification for real-time ethoscope experiments. It is benchmarked against human-generated ground truth.

These functions are rarely called directly, but typically used is in the context of sleep\_annotation.

# Value

an object of the same type as data (i.e. data.table::data.table or behavr::behavr) with additional columns:

- moving Logical, TRUE iff. motion was detected.
- beam\_crosses The number of beam crosses (when the animal crosses x = 0.5 that is the midpoint of the region of interest) within the time window
- max\_velocity The maximal velocity within the time window. The resulting data is sampled at a period equals to time\_window\_length.

#### See Also

• sleep\_annotation – which requieres a motion detector

6 sleep\_annotation

sleep\_annotation

Score sleep behaviour from immobility

#### **Description**

This function first uses a motion classifier to decide whether an animal is moving during a given time window. Then, it defines sleep as contiguous immobility for a minimum duration.

#### **Usage**

```
sleep_annotation(data, time_window_length = 10,
    min_time_immobile = 300, motion_detector_FUN = max_velocity_detector,
    ...)
sleep_dam_annotation(data, min_time_immobile = 300)
```

#### Arguments

data

data.table containing behavioural variable from or one multiple animals. When it has a key, unique values, are assumed to represent unique individuals (e.g. in a behavr table). Otherwise, it analysis the data as coming from a single animal. data must have a column t representing time.

time\_window\_length

number of seconds to be used by the motion classifier. This corresponds to the sampling period of the output data.

min\_time\_immobile

Minimal duration (in s) of a sleep bout. Immobility bouts longer or equal to this value are considered as sleep.

motion\_detector\_FUN

function used to classify movement

... extra arguments to be passed to motion\_classifier\_FUN.

#### **Details**

The default time\_window\_length is 300 seconds – it is also known as the "5-minute rule". sleep\_annotation is typically used for ethoscope data, whilst sleep\_dam\_annotation only works on DAM2 data. These functions are *rarely used directly*, but rather passed as an argument to a data loading function, so that analysis can be performed on the go.

#### Value

a behave table similar to data with additional variables/annotations (i.e. moving and asleep). The resulting data will only have one data point every time\_window\_length seconds.

#### References

• The relevant rethomic tutorial section – on sleep analysis

sleep\_annotation 7

#### See Also

- motion\_detectors options for the motion\_detector\_FUN argument
- bout\_analysis to further analyse sleep bouts in terms of onset and length

#### **Examples**

```
dt_one_animal <- toy_ethoscope_data(seed=2)</pre>
###### Ethoscope, corrected velocity classification ########
sleep_dt <- sleep_annotation(dt_one_animal, masking_duration=0)</pre>
print(sleep_dt)
# We could make a sleep `barecode'
## Not run:
library(ggplot2)
ggplot(sleep_dt, aes(t,y="Animal 1",fill=asleep)) +
                                    geom_tile() + scale_x_time()
## End(Not run)
###### Ethoscope, virutal beam cross classification ########
sleep_dt2 <- sleep_annotation(dt_one_animal,</pre>
                             motion_detector_FUN=virtual_beam_cross_detector)
## Not run:
library(ggplot2)
ggplot(sleep_dt2, aes(t,y="Animal 1",fill=asleep)) +
                                    geom_tile() + scale_x_time()
## End(Not run)
###### DAM data, de facto beam cross classification ######
dt_one_animal <- toy_dam_data(seed=7)</pre>
sleep_dt <- sleep_dam_annotation(dt_one_animal)</pre>
## Not run:
library(ggplot2)
ggplot(sleep_dt, aes(t,y="Animal 1",fill=asleep)) +
                                    geom_tile() + scale_x_time()
## End(Not run)
```
